# A Graphical Tool for Detection of Outliers in Completely Randomized, Unreplicated $2^{k}$ And $2^{\text {k-P }}$ Factorials 

Tony Cooper (SAS, Inc.),
Doug Sanders, Cheryl Hild developed and published the idea

## Outline of Presentation

- Stating the Issue
- Unreplicated $2^{k} \& 2^{k-p}$ Designs
» Common in Industry
» Provide useful information using limited resources
- Addressing the Issue
- Mechanics
» Developing intuition on the information in the plot
- Using the technique on various data sets.
» Simple cases
» Extension to finding more subtle information
- Questions and Reference

## Replicated Design

Constant / Inference Space(Potential Limit on External Validity)

Residual $=y_{i}-\hat{y}_{i} \quad$ Mean Square Error $=\frac{\sum_{i}\left(y_{i}-\hat{y}_{i}\right)^{2}}{d f}$

## 

## But What if Unreplicated?

| Run Order |  |
| :---: | :--- | Treatment

Pseudo Standard Error Methods such as Lenths can be used to evaluate statistical significance

## Rank Order Outlier (ROO) Plot in Unreplicated

- Proposed method to evaluate fit at each point when the design is unreplicated
- Compliments other techniques
- Torres comparison of analysis of ranks to actual Y
- Box (\& Daniel) consideration of the shape of the probability plot.
- An iterative, interactive plotting procedure of effects after data is placed in rank order:
- Develop a feel for the data and order of effects
- Outliers and noise shifts often highlighted
- Non-constant error structures sometimes found
- Does not identify all unit structure issues

## A Plot in Rank Order - How might it look?

- If there was a single large effect, how would the plot look?
- say A has a strong positive effect

## Detecting outliers

- Rank Order Outlier Plots are a tool that primarily evaluates information in the unit structure.
- Use residuals in replicated designs
- Definition of outlier
- Stefansky "An outlying observation is one that does not fit in with the pattern of the remaining observations. In linear models, an observation which differs very much from its fitted values is considered to be an outlier."
- An inconsistency in the pattern of the (modeled) active factors » Includes a "special event"

## Remaining Examples

- Outliers that fall far from the bulk of the data are easy to find; inconsistent patterns within the expected range of experimental results are more difficult to discover and, hence, are often missed. The risk is erroneous conclusions regarding the effect of factors on the experimental response.
- The remainder of the presentation considers "more interesting / subtle" information in the unit structure.

## Example 5: Output

Pareto Plot of Estimates

This may be a critical mix.
A critical mix is when a response occurs only at a particular mix of the factors

## Importance of the technique

- Outliers are responses that do not fit the proposed model. These discrepant points are of great interest.
- Possibilities:
- Unit Structure
» Special Cause
» Background Noise Shift
- Design Structure
» Wrong Model
» Metric
» Critical Mix
- Philosophies:
- A discrepant value should not just be thrown away-it might be trying to tell us something - George Box
- Parallel paths in in the subsequent investigation should consider opportunities in the unit structure as well as the design structure

## Mechanics

- Add Additional Columns To Spreadsheet (DF = \# Columns)
- Sort The Data by Y (smallest to largest)
- Use An Overlay Plot To Graph The Data
- Note Obvious Discontinuities In The Data Plot
» Used in synergy with the Normal Probability Plot
- Iteratively \& Graphically Explore X Columns (Investigation For Subtle Discontinuities)
